IN4MATX 133: User Interface Software

Lecture 6:
DOM Manipulation

Professor Daniel A. Epstein
TA Jamshir Goorabian
TA Simion Padurean

Wrapping up A1

- A lot of GitHub accounts aren't linked to UCI emails on GitHub Classroom
  - Please go to GitHub Classroom and find your UCI email
  - You're probably not on the list if you added the class late—email us and we'll add you
- Make sure your code is committed to the *master* branch
  - `git merge [branchname]`
  - If this doesn't mean anything to you, then your code is committed to master already :-)
- A2 will be posted later this week

Today's goals

By the end of today, you should be able to…

- Debug scoping and hoisting issues in your JavaScript code
- Describe the different roles JavaScript has in client-side and server-side development
- Explain the role of the Document Object Model (DOM)
- Write code which edits the DOM using built-in JavaScript functions
- Write jQuery code to edit the DOM

Some useful JavaScript methods and important notes

null, undefined, and NaN

- `null`: a nonexistent object
  - Therefore it is an object, just unitialized

```
var nullObj = null;

console.log(typeof nullObj); //object
if(!nullObj) {
  console.log("It's falsy");
}
//but it's not equal to false
console.log(nullObj == false); //false
```

https://codeburst.io/understanding-null-undefined-and-nan-b603cb74b44c

null, undefined, and NaN

- `undefined`: an undefined primitive value
  - Therefore it's a primitive value, like a number or a string

```
var undefinedObj;

console.log(undefinedObj); //undefined
console.log(typeof undefinedObj); //undefined
if(!undefinedObj) {
  console.log("It's falsy");
}
//but it's not equal to false
console.log(undefinedObj == false); //false
```

https://codeburst.io/understanding-null-undefined-and-nan-b603cb74b44c

null, undefined, and NaN

- `NaN`: Not a Number
  - Will be the result of any computation on an `undefined` value
  - Or any other impossible computation
  - But it's type is a number (despite the name)

```
console.log('12' - 5); // 7
console.log('word' - 5);// NaN
console.log(undefined * 3);// NaN
console.log(typeof NaN);// number
if(NaN) {
  console.log("It's not falsy!");
}
```

https://codeburst.io/understanding-null-undefined-and-nan-b603cb74b44c

Useful array methods

- JavaScript arrays have stack functions
  - `.push()` and `.pop()` to add and remove the last item, respectively
- Arrays can be combined with `.concat()`
- `.sort()` will sort alphabetically/numerically by default
  - But can take in a comparator
  - For example, sort by the count attribute of an object:

```
array.sort(function(a, b) {
  return a.count - b.count;
});
```

https://medium.com/@DaphneWatson/10-useful-javascript-array-methods-8ffe22e7a959

Useful object methods

- `Object.keys(`object/dictionary/associative-array`)`
  - returns an array containing the keys
  - order is not guaranteed
  - Or `Object.values(`object`)` to get an array of the values
  - Or `Object.entries(`object`)` to get an array containing an array of key, value pairs

```
obj = { pet1: 'Dog', pet2: 'Cat' };

console.log(Object.entries(obj));
// [ ["pet1", "Dog"], ["pet2", "Cat"] ]
```

https://codeburst.io/useful-javascript-array-and-object-methods-6c7971d93230

Scoping

- Variables are scoped to wherever they are defined
    - So if they are within a function, they will only be visible within that function

```
var globalScopedVar = "I'm global!";

function func() {
  var funcScopedVar = "I'm only visible in this
function!";
  return funcScopedVar;
}

console.log(funcScopedVar); //undefined
```

Hoisting

- Functions can be either *declared* or *expressed*, and the two are treated differently in scoping
  - Declaration: `function name() {}`
  - Expression: `var name = function() {}`
- Both are called the same way: `name()`

https://stackoverflow.com/questions/7609276/javascript-function-order-why-does-it-matter

Hoisting

- Variable and function declarations get *hoisted* to execute before the rest of the code
    - Assignment occurs later, where you specify it

```
bar();
var foo = 42;
function bar() {}
//=> is interpreted as
var foo;
function bar() {}
bar();
foo = 42;
```

https://stackoverflow.com/questions/7609276/javascript-function-order-why-does-it-matter

Hoisting

- Function expressions get initialized at the top of the code, but not assigned

```
bar();
function bar() {
    foo();
}
var foo = function() {}
//=> turns into
var foo;
function bar() {
    foo(); //error! not yet defined
}
bar();
foo = function() {}
```

https://stackoverflow.com/questions/7609276/javascript-function-order-why-does-it-matter

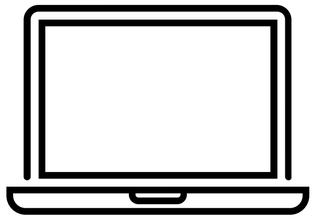
Thus far, JavaScript looks just like any other language

What about JavaScript makes it used so widely on the web?

JavaScript has many functions for editing webpages

Today, JavaScript is used both client-side and server-side

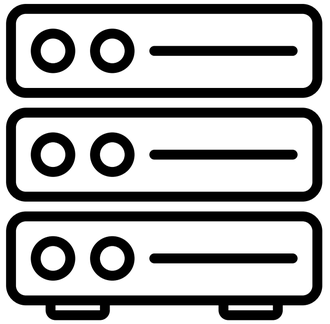
Client-side and server-side JavaScript



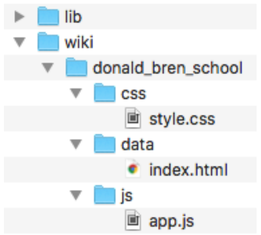
Your device

Request

Response



Web server



Edit what's being rendered
Trigger or react to events

Navigate file system programmatically
Dynamically generate pages or views
Transport, store, or interact with data

Client-side

- Can be seen by the user
- Changes happen in real-time in the browser
- Examples: AJAX, Angular, React, Vue.js

Server-side

- Cannot be seen by the user
- Changes happen on the server in response to HTTP requests
- Examples: Node, ASP.NET

It can be confusing to follow your code if JavaScript is on both sides

Client-side object: Window

- The window object refers to the browser itself.
  You can access properties and execute functions on it

```
/* example properties */
var width = window.innerWidth;   //viewport width
var height = window.innerHeight; //viewport height

/* example functions */
window.alert("Boo!");

var confirmed = window.confirm("Are you sure?");
var quest = window.prompt("What is your quest?”);
```

Bad form, put it on your page instead

Client-side object: Window

- It's possible to use window to control the browser, but behavior varies drastically by browser

```
var xPos = window.screenX; //offset from screen edge
var yPos = window.screenY; //offset from screen edge
var scroll = window.scrollY; //pixels scrolled down
var url = window.location.href; //url for this page

window.scrollTo(0,1000); //scroll to position
window.open(url); //open a new window loading the URL
window.close(); //close window
```

Again, better to keep your program inside the window

Client-side object: Timer

- `window` has functionality for running code on a delay or on an interval

```
function doAfterDelay() { console.log("Surprise!"); }

//run after 1 second
window.setTimeout(doAfterDelay, 1000);

function doRepeatedly() { console.log("Are we there
yet?"); }

//run every 1 second
var timerId = window.setInterval(doRepeatedly, 1000);

window.clearInterval(timerId); //to stop
```

Server-side object: Timer

- Server-side JavaScript usually implements the same functionality without the window object

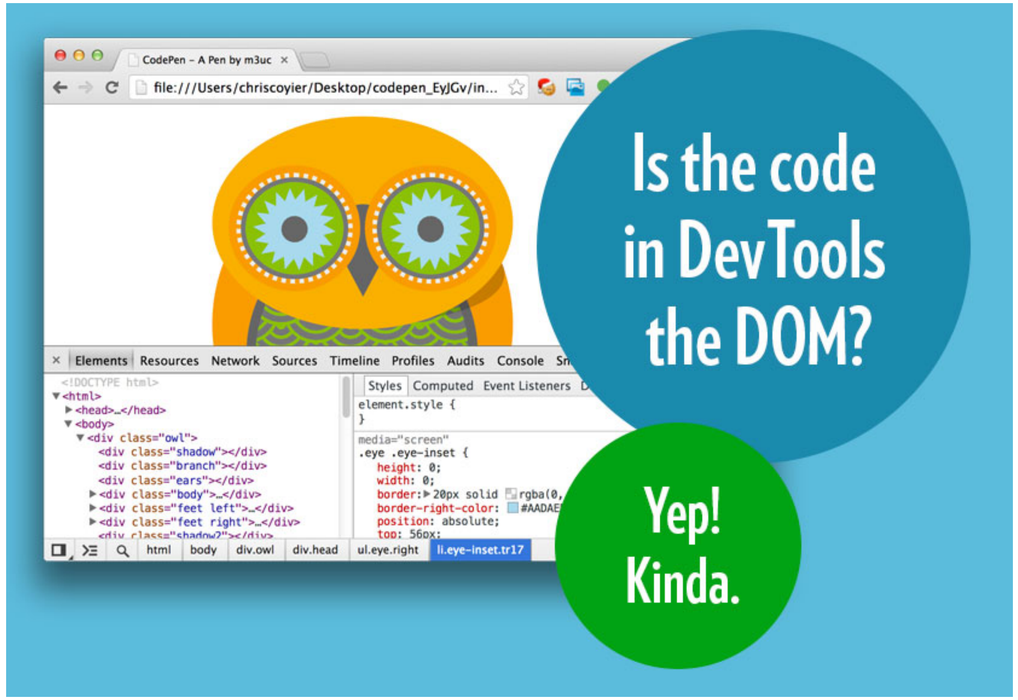
```
setTimeout(doAfterDelay, 1000);

setInterval(doRepeatedly, 1000);

clearInterval(timerId); //to stop
```

HTML Document Object Model (DOM)

- “A standard for how to get, change, add, or delete HTML elements”
- “the HTML you write is parsed by the browser and turned into the DOM”
- Client-side JavaScript can then edit the DOM



https://css-tricks.com/dom/

JavaScript in HTML

- Can insert inline using the `<script>` tag

```
<head>
  <script>
    alert("Hello, world!");
  </script>
</head>
<body>

</body>
```

JavaScript in HTML

- Your script should wait until after the page has loaded
  - Otherwise elements you're trying to access might not exist

```
<head>
  <script>
    function pageLoaded() {
      alert("Page Loaded!");
    }
  </script>
</head>
<body onload="pageLoaded();">

</body>
```

JavaScript in HTML

- Functions can respond to events

```
<head>
  <script>
    function buttonClicked() {
      alert("Button Clicked!");
    }
  </script>
</head>
<body>
  <!--Bad style! Don't do this-->
  <button onclick="buttonClicked()">Click me!</button>
</body>
```

JavaScript in HTML

- Like CSS, better to load an external script

```
<head>
  <script src="js/script.js"></script>
</head>
```

Editing the DOM

- document object model

- Write into the DOM with `document.write`

```
<script>
  document.write("<h1>Hello, World!</h1>");

  var myCourse = "IN4MATX 133";
  document.write("<h1>Hello, " + myCourse + "!");
</script>
```

Selecting elements

- We can reference individual HTML elements by calling selector functions

```
//element with id="foo"
var fooElem = document.getElementById('foo');

//elements with class="row"
var rowElems = document.getElementsByClassName('row');

//<li> elements
var liElems = document.getElementsByTagName('li');
```

Selecting elements

- We can reference individual HTML elements by calling selector functions

```
/*easiest to select by reusing CSS selectors! */
var cssSelector = 'header p, .title > p';

//selects FIRST element that matches css selector
var elem = document.querySelector(cssSelector);

//matches ALL elements that match css selector
var elems = document.querySelectorAll(cssSelector);
```

Editing elements

- Properties and functions of elements can manipulate them

```
/* properties to access the CONTENT of the element */

var elem = document.querySelector('p');

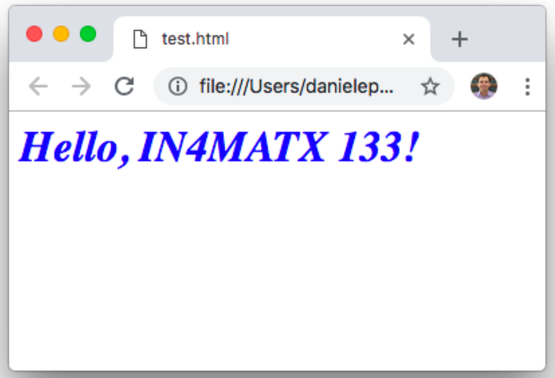
var text = elem.textContent; //the text content of the elem
elem.textContent = "I'm different!"; //change the content

var html = elem.innerHTML; //content including tags
elem.innerHTML = "I'm <strong>different</strong>";

var parent = elem.parentNode; //get the parent node
```

Editing elements

- Can add/remove classes, IDs, and inline style



```
<style>/*Bad form! Just for demo*/
  .title {
    font-style: italic;
  }
</style>
<h1>Hello, IN4MATX 133!</h1>
<script>
  var elements = document.getElementsByTagName("h1");
  for(var i = 0; i < elements.length; i++) {
    elements[i].classList.add("title");
    elements[i].style.color="blue";
  }
</script>
```

Changing the DOM

```
//create a new <p> (not yet in the tree)
var newP = document.createElement('p');
newP.textContent = "I'm new!";

//create Node of textContent only
var newText = document.createTextNode("I'm blank");

var div = document.querySelector('div#container');
div.appendChild(newP); //add element INSIDE (at end)
div.appendChild(newText);

//add node BEFORE element (new, old)
div.insertBefore(document.createTextNode("First!"), newP);

//replace node (new, old)
div.replaceChild(document.createTextNode('boo'), newText);

//remove node
div.removeChild(div.querySelector('p'));
```

Question 

Which snippet would edit the `p` to display “1, 2, 3, 4, 5”?

```
<p class="para" id="intro">1, 2, 3</p>
```

A
```
document.getElementById("intro").append(", 4, 5");
```

B
```
document.getElementsByClassName("para").innerHTML("1, 2, 3, 4, 5");
```

C
```
document.getElementsByTagName("p")[0].innerHTML("1, 2, 3, 4, 5");
```

D Two of the above

E All of the above

Validating data

- Check form fields before sending to a server
  - Provide instant feedback, reduce server back-and-forth

```
<script>
  function validateForm() {
    var x = document.forms["myForm"]["fname"].value;
    if(x==null || x=="") {
      alert("Name must be filled out");
      return false;
    }
  }
</script>
<form name="myForm" onsubmit="return validateForm()" method="post">
  <label>Name: </label>
  <input type="text" name="fname">
  <input type="submit" value="Submit">
</form>
```

Gather and use information

- Remember: this is client-side!
    - Storage would require sending to a server, which people can block in their browsers

```
<script>
  var x = document.getElementById("demo");
  function getLocation() {
      if (navigator.geolocation) {
          navigator.geolocation.getCurrentPosition(showPosition);
      } else {
          x.innerHTML = "Geolocation is not supported by this browser.";
      }
  }
  function showPosition(position) {
      x.innerHTML = "Latitude: " + position.coords.latitude +
      "<br>Longitude: " + position.coords.longitude;
  }
</script>
```

How do we make interactive pages?

Listeners

- Can attach a listener to that method, specifying that we want to do something when that element causes an event

```
//respond to "click" events
elem.addEventListener('click', callback);

//often use an anonymous callback function
elem.addEventListener('click', function(){
  console.log('clicky clicky!');
});
```

Listeners

- Listener callback function will be passed an **event** parameter
  - Sometimes useful, but can often be ignored

```
elem.addEventListener('click', function(event) {
    console.log('You clicked me!');

    //get what was clicked;
    var clickedElem = event.target;
});
```

Remember, parameters are optional

The “target” (source) of the event

Event types

```
'click'      //mouse or button clicked

'dblclick'   //double-clicked

'hover'      //mouse hover

'focus'      //element gains focus (important!)

'mouseenter' //mouse is moved over an element

'mouseleave'  //mouse leaves the element

'mousedown' //mouse button is pressed

'keydown'    //key is pressed

//... and more!
```

https://developer.mozilla.org/en-US/docs/Web/Events

Manipulation in pure JavaScript is verbose

- If you’re editing a lot of tags, your code can get very long and difficult to read

jQuery

- Predefines methods for manipulating the DOM
  - Include before your own script
- Remember:
  - Integrity: hashes to ensure the downloaded file matches what's expected
  - Crossorigin: some imports require credentials, anonymous requires none

```
<script
  src="https://code.jquery.com/jquery-3.3.1.min.js"
  integrity="sha256-FgpCb/KJQlLNfOu91ta32o/NMZxltwRo8QtmkMRdAu8="
  crossorigin="anonymous"></script>
```

jQuery selector

- Use the `jQuery()` function to select DOM elements.
  The parameter is a CSS selector String (like `querySelector`)
    - More common to use the `$()` shortcut

```
//selects element with id="foo" (e.g., <p id="foo">)
var fooElem = jQuery('#foo');

//selects all <a> elements (returns an array)
var allLinksArray = jQuery('a');

//selects element with id="foo" (e.g., <p id="foo">)
var fooElem = $('#foo');

//selects all <a> elements (returns an array)
var allLinksArray = $('a');
```

jQuery selector

- jQuery handles all CSS selectors, as well as some additional pseudoclasses

```
$('#my-div') // by id
$('div') // by type
$('.my-class') // by class
$('header, footer') // group selector
$('nav a') // descendant selector
$('p.red') // scoped selector

$('section:first') // first <section> element
                   // not a css selector!
```

jQuery and elements

- Similar to pure JavaScript, jQuery provides methods to access and modify attributes and CSS

```
//Pure JavaScript
var txt = document.querySelector('#my-div').textContent;
document.querySelector('#my-div').textContent = 'new info!';
document.querySelector('#my-div').innerHTML = '<em>new html!
</em>';

//jQuery
var txt = $('#my-div').text();          //get the textContent
$('#my-div').text('new info!');         //change the textContent
$('#my-div').html('<em>new html!</em>'); //change the HTML
```

Changes apply to <u>all</u> selected elements

jQuery and the DOM tree

```
//create an element (not in DOM)
var newP = $('<p class="new">This is a new element</p>');

//add content to DOM
$('main').append(newP); //add INSIDE, at end
$('main').append('<em>new</em>'); //can create element on the fly

$('main').prepend('<em>new</em>'); //add INSIDE, at beginning

$('main').before('<header>'); //insert BEFORE

$('footer').insertAfter('main'); //insert target AFTER param

$('main').wrap('<div class="container"></div>'); //surround

$('footer').remove(); //remove element
$('main').empty(); //remove all child elements
```

Works without closing tag

Selects existing element, so will move!

jQuery event handling

- jQuery also provides convenience methods for registering event listeners

Like `addEventListener('click')`

```
$('#button').click(function(event) {
    console.log('clicky clicky!');

    //what was clicked
    var element = $(event.target);
});
```

`event.target` is equivalent to `this`

Get as jQuery-style element to call jQuery methods on it ("wrap it")

Document ready: JavaScript

- Remember earlier: your script should wait until after the page has loaded
  - Otherwise elements you're trying to access might not exist

```
<head>
  <script>
    function pageLoaded() {
      alert("Page Loaded!");
    }
  </script>
</head>
<body onload="pageLoaded();">

</body>
```

Document ready: jQuery

```
$(document).ready(function() {
  //your program goes here
  //this need not be an anonymous function

});
```

Document ready: jQuery

```
//shortcut: just pass the function to the jQuery method
$(function() {
  //your program goes here
  //this need not be an anonymous function

});

//shortest cut: use the abbreviated syntax
$(() => {
  //your program goes here
  //this need not be an anonymous function

});
```

Importing JavaScript

- When your script uses document ready, convention is to load it in the `<head>` tag
  - Important to think about ordering, particularly for libraries
  - e.g., import JQuery before you use it in a script

```
<head>
  <script src="https://code.jquery.com/
jquery-3.3.1.min.js"></script>
  <script src="index.js"></script>
</head>
```

jQuery effects

- jQuery supports adding transitions to modify the appearance of effects

```
$('#id').fadeIn(1000);    //fade in over 1 second
$('#id').fadeOut(500);    //fade out over 1/2 sec
$('#id').slideDown(200); //slide down over 200ms
$('#id').slideUp(500);    //slide up over 500ms
$('#id').toggle();        //toggle whether displayed
```

jQuery utility functions

- jQuery includes many utility functions to simplify syntax

```
//check if an item is in an array
$.inArray(4, [3,4,3] );

//this is like .filter, but works on old browsers
$.grep( [3,4,3], function(item) {
   return item > 3;
});

//iterate over arrays or objects -- works for either!
$.each( [1,3,3], function(key, value) {
   console.log('Give me a '+value);
});

$.each( {dept:'IN4MATX',num:'133'}, function(key, value) {
   console.log(key+' name: '+value);
});
```

http://api.jquery.com/category/utilities/

Even more utilities: Lodash

- A handy library for working with basic data structures

```
_.flatten([1, [2, [3, [4]], 5]]);
// => [1, 2, [3, [4]], 5]

var zipped = _.zip(['a', 'b'], [1, 2], [true, false]);
// => [['a', 1, true], ['b', 2, false]]

_.unzip(zipped);
// => [['a', 'b'], [1, 2], [true, false]]
```

https://lodash.com/

Today's goals

By the end of today, you should be able to…

- Debug scoping and hoisting issues in your JavaScript code
- Describe the different roles JavaScript has in client-side and server-side development
- Explain the role of the Document Object Model (DOM)
- Write code which edits the DOM using built-in JavaScript functions
- Write jQuery code to edit the DOM
